

The Role of Officer Gender in Responses to Domestic Violence

Maria Mercedes Ponce de Leon *

[Click here for the most recent version](#)

Abstract

Do female officers respond differently to domestic violence calls than their male counterparts? I empirically analyze this question using novel data from Seattle. Patrol officers are quasirandomly assigned to incidents, which allows me to identify that causal effect of officer gender on policing outcomes. Teams with at least one female officer are more likely to find the initial report credible: Incidents described as domestic violence by the call taker are more likely to retain that designation and to be recorded as a crime. In less severe cases, where officers have greater discretion, the presence of a female officer also increases the probability of an arrest being made. These differences lead to lower rates of future victimization in the short run. I also find evidence that teams with female officers exert more effort at the scene than their all-male counterparts when responding to these incidents. Taken together, my findings highlight the importance of gender diversity in law enforcement and suggest that the strategic dispatch of female officers could enhance the effectiveness of police responses to domestic violence.

*Brown University, maria_ponce_de_leon@brown.edu I thank Brian Knight, Anna Aizer, Jesse Bruhn, and numerous seminar and conference participants for valuable feedback and suggestions. I also thank the Seattle Police Department for granting me access to their administrative data and the Seattle Police Department staff for providing invaluable insights into the context and the data

1 Introduction

Domestic violence is pervasive: In the US alone, 114 million people reported experiencing it at least once in their lifetime (CDC, 2024). However, historically, it has not been taken seriously by law enforcement, who have often dismissed it as a private family issue.¹ A key feature of domestic violence is that it is highly gendered: 85% of victims of domestic violence are female (Catalano, 2012). On the other hand, those assisting these victims are usually men, since law enforcement remains a very male-dominated field: nationwide 87.5% of officers are male (Federal Bureau of Investigation, 2017).

These gender disparities raise important questions about the efficacy of law enforcement. Individual officers have a large degree of discretion when responding to incidents, which could lead to worse outcomes if male officers discount the experiences of female victims or female victims feel less comfortable disclosing case details to male officers. It has long been theorized that female officers are better-suited to investigating crimes against women. Furthermore, while there is compelling causal evidence that female representation matters for law-enforcement outcomes (Miller and Segal, 2019), the existing literature on individual officer behavior in the context of these crimes is sparse and correlational in nature (Chu and Sun, 2014, Sun, 2007, Kennedy and Homant, 1983).

In this paper, I study whether female and male officers handle domestic violence calls for service differently. Specifically, I examine differences in officer reporting rates and enforcement activity by the gender composition of the team of responding officers. To do so, I focus on the likelihood of the incident being labeled as domestic violence by the officers and being reported as a crime, as well as the probability of an arrest being made at the scene.

¹This has been documented extensively by the media. See, for example, <https://theappeal.org/champaign-police-domestic-violence-laws-invisible-institute-illinois-public-media/>, <https://www.theguardian.com/society/2021/sep/17/no-support-domestic-abuse-victims-on-being-ignored-by-police>

I study this question in the context of Seattle, for which I have detailed administrative data provided by the Seattle Police Department. The data include the universe of 911 calls made in the city between 2012 and 2023, linked with information on every officer that reported to the scene of the incident and on every crime committed. To address endogeneity, I exploit the conditional random assignment of officers to incidents, which stems from the dispatching procedures in place in Seattle. I then compare calls for domestic violence where at least one female officer was dispatched to calls where all the responding officers were male.

I find that when a female officer is present, officers take domestic violence calls for service more seriously than when responding officers are only men. When at least one female officer is dispatched, it is less likely that the officers will remove the domestic violence label from the classification of the incident. Furthermore, dispatching at least one female officer also increases the likelihood that the incident will be reported as a crime, the first step needed to bring charges against the offender. While there is no difference in the overall probability of an arrest being made, it is important to note that in Seattle, arrests are mandatory in domestic violence cases involving assault or protective orders, while they are discretionary in every other situation. When I separately analyze the incidents in which arrest is mandatory and discretionary, a different pattern emerges.

The results appear to be driven primarily by cases in which officers have the greatest discretion. For these incidents, I find that dispatching a female officer results in a 3.5% higher likelihood of the classification remaining domestic violence, a 5.1% higher likelihood of the incident being reported a crime rather than a civil matter, and a 7.9% higher likelihood of an arrest being made at the scene. For incidents that were more severe at the time the call was placed, namely those related to assaults or the breaking of a no-contact order, I only find differences in the likelihood of the final classification of the incident being domestic violence and a smaller difference in the probability of a criminal report being written.

These results are robust to the inclusion of additional controls for officer characteristics,

namely the average experience of the first responding officers and a measure of the racial diversity of the team. This is consistent with the officers initially dispatched being randomly assigned. The results are also robust to a variety of alternate specifications of the model that control more and less stringently for location and time characteristics.

The differences in how teams with female officers handle domestic violence calls appear to lead to a reduction in the probability of a future incident of domestic violence. This effect is concentrated in the short run. Specifically, when at least one female officer is dispatched, it is less likely that there will be a subsequent call for domestic violence within 30 days of the original incident. The reduction is driven by a 2.9% lower likelihood of future victimization within the first 15 days following the original incident.

I find evidence that the results found are partly driven by teams with female officers taking every incident more seriously than their all-male counterparts. When I examine calls involving violence between two or more people but that the call-taker did not classify as domestic violence, I still find that teams including at least one female officer are more likely to label the incident as domestic violence and to report it as a crime.² However, the results found for arrests in cases of disturbances or threats related to domestic violence appear to be driven by a change in behavior when dispatched to domestic violence calls. For other violent incidents, in fact, I detect no significant difference by team gender composition in the propensity to arrest on the scene.

The main results are also consistent with teams with female officers exerting more effort when dispatched to domestic violence calls than all-male teams. I study effort provision using two different measures: the time spent at the scene and the propensity to list multiple offenses when writing criminal reports. Both of these measures capture the degree of thoroughness and engagement in handling domestic violence cases. I find that teams with female officers spend 4% longer at the scene and are also more likely to list additional smaller

²The incidents included are disturbances, threats, assaults and fights not related to domestic violence.

charges in criminal reports, which, according to the FBI, is among the most important optional actions officers can take to increase the likelihood of prosecution in domestic violence cases (Nelson 2013).

This paper also contributes to the literature on the effects of diversity on individual welfare by demonstrating why gender diversity is important in police departments. It has been shown that having teachers (Dee, 2005) and doctors (Cabral and Dillender, 2024, Ye and Yi, 2023) that share your same race or gender and lead to improved outcomes. However, when it comes to policing, most of this literature has focused on the impact of racial diversity, while gender diversity has been relatively under-explored. A large body of research studies the effect of officer race on different police decisions including traffic stops and issuing fines (Antonovics and Knight, 2009; West, 2018; Goncalves and Mello, 2021; Anwar and Fang, 2006), use of force (Hoekstra and Sloan, 2022, Johnson et al., 2019) and arresting decisions (Weisburst, 2022; Rivera, 2022). McCrary (2007) further looks at the effect of affirmative action programs in police departments on police performance. The most closely related paper is Miller and Segal (2019), who use aggregate data and find that the introduction of women into the police force raised domestic violence reporting and reduced intimate partner homicides. This study builds on those findings by using rich incident-level administrative data to uncover *why* gender diversity matters in policing and *how* it can lead to improved outcomes for victims.

I also contribute to the literature on domestic violence, by providing the first causal estimate of the importance of the gender of the dispatched officers. A considerable body of research has studied determinants of domestic violence, such as labor market conditions (Aizer, 2010; Erten and Keskin, 2024; Bhalotra et al., 2021), culture (Alesina et al., 2016) and unexpected losses of local sports teams (Card and Dahl, 2011); as well as the effect of different policies and responses to domestic violence such as no drop policies (Aizer and Dal Bo, 2009), pressing charges (Black et al., 2023) and arrests (Iyengar, 2009, Amaral et al., 2023, Chin and Cunningham, 2019). Observational studies in criminology have also

suggested that the presence of female officers might affect victim’s outcomes ([Stalans and Finn, 2000](#); [Chu and Sun, 2014](#); [Sun, 2007](#)).

The rest of the paper is organized as follows. Section 2 provides relevant institutional background on how the Seattle Police Department dispatches officers to calls for service, as well as how they handle domestic violence incidents. In section 3, I provide more details on my data and empirical strategy. Section 4 presents the main results, and section 5 explores the mechanisms behind the results and test their robustness. Section 6 concludes.

2 Institutional Background

This section provides details on the relevant institutional background. I begin by explaining how the dispatch procedures work within the Seattle Police Department, which is critical for our research design. I then explain what directives are in place within the Seattle Police Department for the handling of domestic violence incidents.

2.1 Dispatch procedures in Seattle

Seattle is located in Washington State. As of 2024, it has a population of 759,915 people, making it the 18th most populated city in the United States and thus comparable in size to other major US cities ([World Population Review, 2024](#)). It is further representative in terms of the share of female officers employed by the city’s police department. By taking the 2013 wave of the LEMAS survey, I obtain the share of full-time sworn police officers with arresting power who are female, for all US police departments serving at least 250,000 people. Figure [A.I](#) shows where SPD lies in the distribution of this variable. Seattle, which is denoted by the red vertical line, is not an outlier in the share of female officers; rather, it places around the middle of the distribution, suggesting that Seattle’s police force is broadly representative of large cities in the U.S along this dimension.

Seattle is organized into five precincts, each with its own dedicated dispatcher responsible for handling service calls originating within their precinct's boundaries. To distribute the workload among patrol officers, these precincts are then further divided into sectors and beats, with each sector containing three beats. Figure 1 depicts these geographic units. Each day is also divided into three shifts ³. Patrol officers are always assigned to patrol in a specific sector and precinct, and during a specific shift. Sometimes they will be further assigned a beat within the sector, while other times they will float between the 3 beats contained within their sector. On any given day, within a beat, there will be one patrol car that is only patrolling that beat, and the officer(s) in that car are called the primary beat officer(s). ⁴ On that same beat there will typically also be at least one other car patrolling that beat, corresponding to officer(s) assigned to float between the beats in the same sector. ⁵

Every 911 call will be routed to a designated radio dispatch zone based on their location. The call taker will then record important information for the responding officers such as a description of the incident and details on the exact location where it is taking place. Based on the information shared, the call taker will then assign a priority level and an initial incident type classification. The priority level assigned ranges from 1 (most urgent) to 7 (least urgent), and will determine how quickly officers respond, with more urgent calls being dispatched first. The initial classification of the incident is done by choosing from a list the call type code that most closely represents the circumstances of the situation or the nature of the request. As the call taker collects this information, it will be shared electronically with a dispatcher, who will start to coordinate a response with the necessary emergency service.

Conversations with SPD confirmed that when deciding which officer(s) to dispatch to

³The three shifts are as follows: first shift is from 3 AM to 12PM, second shift is from 11-8PM and finally the third shift is from 7 PM to 4 AM

⁴Within that car, there may be more than one officer

⁵According to conversations with staff from SPD, the number of patrol cars that are floating at any given time depends on staffing. In my data I have the exact sector assignment of officers between 2016 to 2023, and I can see that the average number of cars in each sector in each shift is more than 6, which would mean there are, on average, 3 cars corresponding to the primary beat officer(s) of each beat, plus at least 3 patrol cars floating between beats.

each call, the most relevant geographic level is the sector, of which there are 17 in the entire city. Calls coming from within a specific sector will be handled by officers assigned to patrol in that sector, unless none of them are available ⁶. When deciding which officer(s) from the sector to assign to the call, the dispatcher will take into consideration proximity, availability and number of patrol cars needed ⁷. While dispatchers have some discretion in this choice, the primary goal is to take care of the call as fast as possible.

These dispatch procedures point to there being conditional random assignment of officers to calls. Specifically, within a sector and in a specific point in time, which officers you get (and more importantly the gender of those officers), should be as-good-as random. My empirical strategy will then rely on the assumption that sector-by-time fixed effects should allow me to isolate as-good-as random variation in the gender of the responding officers. In section 3.2 I explain more in detail how I do this, as well as provide evidence in favor of the validity of this assumption.

2.2 Domestic Violence in Seattle

The Seattle Police Department defines domestic violence as a pattern of harmful behavior by one person intended to control another person within a romantic, intimate or family/household member relationship ⁸. This abuse can take various forms, including emotional manipulation and physical harm. In Washington State, where Seattle is located, it is against the law for a partner to physically harm you, force you into sexual activity, threaten to hurt or kill you or your children, or destroy your property. This means that, for example,

⁶A patrol car from another sector might also be dispatched in cases in which the number of cars necessary (which depends on the severity of the call) is higher than the number of patrol cars available in the sector.

⁷In theory, dispatchers are meant to consider who the primary beat officer(s) of the beat from which the call is coming from are when deciding who to assign the call to. However, conversations with a an SPD employee who currently works in public affairs and was previously a patrol officer, revealed that this is not always respected. This was confirmed by the Research Scientist who shared assignment data with us and stated that the beat is not relevant. This is also confirmed by the data shared on where each officer was assigned, in which the beat is not even listed

⁸For more details, see <https://www.seattle.gov/police/need-help/crimes-against-persons/domestic-violence/what-is-domestic-violence>

emotional abuse can be considered domestic violence, but not illegal if the perpetrator does not threaten the victim or their children, or if police does not believe these threats took place.

When assigning an initial classification to the incident, the call taker can also add a *domestic violence* label, if they believe the assault is domestic violence (based on the relationship between the alleged offender and victim), in which case the classification assigned will be *Assault - Domestic Violence*. To conduct my analysis and study whether police responses to domestic violence vary depending on the gender of the officer, I focus my attention to the set of calls which the call taker believed to be domestic violence related. I do so that my sample is exogenous to what officers believe to be domestic violence.

Upon arriving at the scene, the patrol officer(s) might determine that the domestic violence label added by the call taker was incorrect. This could happen, for instance, if they find that the relationship between the victim and perpetrator doesn't meet the criteria defined by the Seattle Police Department for domestic violence (e.g., they are friends rather than intimate partners or family members), or if they conclude the incident is not part of a pattern of harmful behavior. In the time frame studied, this happens in around 40% of cases, and the most common new classification by the officer being *Disturbance - Other*⁹.

Also once at the scene, the responding officer(s), after gathering evidence and speaking with the complainant, alleged offender and possible witnesses, will also determine whether a crime took place or not. In the case they determine that no illegal activities took place, they will write an incident report explaining the situation and how they handled it. This could happen, for instance, if the victim was emotionally abused, but officers do not believe that the perpetrator threatened the safety of the victim. In the case they determine that a crime took place, they will write a criminal report and list all crimes they believe took place. Listing multiple charges in the criminal report is among the most important optional

⁹In over 97% of cases in which officers classify the incident as *Disturbance - Other*, they also report it as a civil matter as opposed to a crime.

actions responding officers can take to increase the chances of prosecution, especially when it comes to domestic violence cases (Ferguson and Douglas, 2016 , Nelson, 2013 ¹⁰). Further, in cases in which officers are responding to a domestic violence call and have probable cause to believe that a crime took place should seize all firearms that were used or threatened to be used during the offense.

When incidents are classified as domestic violence, resources are available within the SPD to further assist victims. Specifically, SPD has two teams that can offer support services to domestic violence victims. Community Service Officers (CSOs) can respond to the scene of domestic violence incidents once the police has completed their work, and provide food, shelter, phones, clothing, hotel room vouchers, transportation, and emergency shelters for victims. The Victim Support Team (VST) is comprised of social workers that have achieved their master's degree and work directly with DV Victims. They offer short term advocacy and connections to resources in the community and within the Criminal Justice System. They also assist in admitting victims of domestic violence and their children into confidential, protective shelters.

If responding officers disagree with the domestic violence label and remove it, the available resources are reduced. For example, shelters for domestic violence victims are no longer an option, and advocates from the VST will no longer be called and the services they provide will no longer be available to victims ¹¹. Leaving the domestic violence label will also be consequential for the perpetrator. A conviction for a domestic violence charge can mean the loss of gun rights, supervised probation for two years and having to attend court ordered treatment programs or counseling ¹², Further, a misdemeanor DV charge is automatically

¹⁰This was also confirmed to us by a coordinator of law enforcement training from the Rhode Island Coalition Against Domestic Violence.

¹¹There is a possibility that their services are provided to victims if the victim themselves calls or emails the VST and ask for help. However, this requires that the victims know about the VST and how to get in touch with them.

¹²Probation counselors oversee the completion of court-mandated treatment programs and counseling. Domestic violence offenders are required to report in person each month until they demonstrate consistent compliance with their treatment plan. Judges may also mandate additional interventions such

upgraded to a felony if the offender has at least two previous convictions for other crimes of DV (such as for assault or harassment) within the previous ten years.

In cases in which the responding officers determine that the offense was in fact domestic violence, the law in Washington state requires that they make an arrest if they have probable cause to believe that an assault took place within four hours prior their arrival ¹³. Arrest is also mandatory in cases in which an offender breaks a no contact order. In every other case, arrest is discretionary. In my data, I am able to precisely distinguish between cases in which the officer arrested the offender because they claimed the characteristics of the incident meant it was mandatory to do so, and when they claimed it was a discretionary decision. In the case an arrest is made and charges are filed, the victim will not have the authority to drop them.

3 Data and Empirical strategy

Drawing on detailed administrative data from the Seattle Police Department (SPD) from 2012 to 2023, I compare domestic violence related calls for service in which at least one female officer was dispatched, to those in which all the responding officers were male. My identification strategy relies on as-good-as-random variation in officer assignment to 911 calls, which stems from the way in which officers are dispatched to calls.

3.1 Data and outcomes of interest

I have detailed administrative data from the Seattle Police Department obtained through a Research Agreement. The data includes the universe of all calls for service from 1/1/2012

as domestic violence treatment, substance abuse counseling, parenting classes, or sexual deviance therapy. Source: <https://www.seattle.gov/courts/programs-and-services/specialized-courts/domestic-violence-intervention-project/what-happens-in-cases-of-domestic-violence>

¹³If the officer determines that two or more parties assaulted each other, then they will arrest only the person they believe was the primary aggressor.

to 12/31/2023, and I am able to follow incidents from the time the call is placed until the call is cleared by police.

For each call, I observe the exact date and time when it was placed, as well as when each officer were dispatched, when and how the call was cleared, and geographic information on where the call was coming from that includes the beat and blurred latitude and longitude ¹⁴. Importantly, I am also able to see how the call taker classified the incident when the call was first placed, and the reclassification by officers ¹⁵. I also have information on every police officer that was dispatched to each call, including a unique officer identifier which allows me to follow officers over time in different incidents, as well as their race, gender, and the year the officer joined the police force. For 2015 onwards, for any given officer on any given day, I know where in the city they were assigned to patrol, as well as during which shift. Finally, I am also able to identify for each call for service, whether officers reported the incident as a crime, or whether they claimed it was a civil matter ¹⁶. For the subset of incidents that officers reported as a crime, I also have the exact address where the incident took place, as well as demographic information on victims and offenders that includes their gender, race and age. While I only have access to the gender of the complainant in these cases (i.e. the cases in which the incident was not reported as a crime), since most victims of domestic violence are women, I view the results as largely representing differential response by officer gender to incidents involving female victims.

I use this information to study service provision along several dimensions. The first of these is the final classification of the incident, as determined by the team of responding officers. As previously mentioned, once at the scene and after conducting an investigation

¹⁴The blurred coordinates place us at the middle of the street where the incident took place.

¹⁵The responding officers must assign this classification immediately after leaving the scene and before becoming available to respond to other calls.

¹⁶Once police arrives at the scene, the first thing they do is conduct an investigation to determine whether a crime has been committed. If they determine that it was, they will write a criminal report detailing what crimes were committed and why they came to that conclusion, if they determine that no crime took place, then they write an incident report in which they detail the situation

of the scene, police officers can determine that the DV label assigned by the call taker is incorrect and thus claim that the incident was not actually domestic violence. Secondly, I look at whether the incident is reported as a crime, or if, instead, the responding officers claimed that the incident was a civil matter ¹⁷. This corresponds to the first stage needed to be able to file charges against the offender. Finally, I will also look at whether an arrest is made at the scene or not. Recent literature ([Amaral et al., 2023](#), [Chin and Cunningham, 2019](#)) has shown that arresting the offender can lead to reduced future victimization. Thus, I will take the action of making an arrest as better service provision.

Table 1 summarizes the data. The first column covers the full sample of 911 calls that the call taker classified as domestic violence, while column 2 restricts the sample to the ones in which at least one female officer was dispatched and column 3 to the calls in which only men were dispatched¹⁸. The sample includes 98,644 calls for service that were classified as domestic violence by the call taker. Of these, 19.6% of them had at least one female officer initially dispatched ¹⁹. Incidents that see at least one female officer are of similar priority and occur in census block groups with comparable demographic characteristics. Additionally, there is no significant difference in the likelihood of teams including a racial minority when at least one female officer is present. However, teams with at least one female officer do tend to have officers with slightly less patrol experience on average (7.7 years compared to 8.6 years) ²⁰. I note that the average number of officers dispatched is higher in incidents that see at least one female officer, a mechanical outcome given that only around 15% of patrol officers are female. To address this, in the research design I will include a fixed effect for the number of officers dispatched. The final three rows of table 1 show that teams including at least

¹⁷Appendix figure [A.II](#) shows the percent of cases classified as domestic violence by the call taker that the officers reported as crimes, separately by whether they kept the domestic violence label or not. It shows how the cases where they take out the domestic violence label are also the cases that they report least as crimes.

¹⁸In order to define this sub-samples, I use only the officers that were initially dispatched, as the decision to ask for backup can be endogenous.

¹⁹This is higher than the percent of female officers in the force (which in my period of analysis is around 14.5%) because female officers are not equally distributed across the city. Appendix figure [A.III](#) shows the percent of calls where at least one female officer was initially dispatched for each beat in the city

²⁰Given this, I control for the average experience of teams in robustness checks in section [5.1](#)

one female officer are more likely to classify incidents as domestic violence, report incidents as crimes, and arrest suspects on the scene. These differences are formally tested in section 4.

3.2 Regression Model

The identification strategy relies on as-good-as-random variation in the gender composition of responding officers. Specifically, I rely on the assumption that conditional on sector by time fixed effects, the gender composition of responding officers should be as good as random. I believe this assumption is reasonable given the dispatching procedures that are in place in Seattle, and I also empirically validate it in order to assess the validity of the research design. In order to estimate the effect of having at least one female responding officer in domestic violence calls for service, I estimate the following model:

$$Y_i = \beta_0 + \beta_1 \mathbb{1}\{Has\ Female\ Officer\}_i + \delta_{symw} + \gamma_s + \gamma_n + \epsilon_i \quad (1)$$

Where Y_i will represent the different outcome variables. The main outcomes of interest are whether the final classification by the officers includes the domestic violence label, whether the incident gets reported as a crime, and whether an arrest is made at the scene. $\mathbb{1}\{Has\ Female\ Officer\}_i$ is an indicator that is equal to one when, among the responding officers that were first dispatched, there is at least one female. δ_{symw} are sector by year by month by week fixed effects, and γ_s are shift fixed effects. γ_n corresponds to a fixed effect for the number of officers that were initially dispatched ²¹, which I include because the higher the number of officers dispatched, the higher the likelihood that there will be at least one female officer. Standard errors are clustered at the team of responding officers level to allow observations to be correlated across cases for a particular team of responding officers.

²¹When cleaning the data, I exclude incidents with extreme values of this variable. Specifically, I drop observations with the top 1% in terms of number of officers first dispatched. This leaves us with 99% of incidents, all of which had either 1, 2 or 3 officers first dispatched.

3.3 Evidence of Conditional Random Assignment

The process described in section 2.1 that determines officers assignment suggests conditional random assignment of officers to calls. Specifically, it suggests that sector-by-time fixed effects should isolate as-good-as-random variation in the gender of the first dispatched responding officers. In this subsection, I empirically test the validity of my research design in a few different ways. Since the selection of officers to calls through which I expect to have conditional random assignment only applies to the first dispatched officers, I restrict my attention to only them. Hence, I define an incident as having at least one female officer if among the first dispatched officers there is at least one female officer. This means that I will perform an intent-to-treat analysis.

While the dispatcher’s main concern should be, according to the dispatch center ²², to dispatch an officer as soon as possible, one might be concerned that, when the call is related to domestic violence, they could prioritize sending a female officer instead. I test whether incidents related to domestic violence are more likely to get a female officer dispatched, as opposed to only males, compared to other incidents. I follow the specification in section 3.2 and regress an indicator for whether the call taker believed that the incident was domestic violence against an indicator for whether at least one of the officers in the car was a female, while controlling for sector-year-month-week fixed effects and shift fixed effects. Table 2 shows the results from this test, and it shows how cars with female officers are not more likely than cars with only male officers to get dispatched to calls for domestic violence. The coefficient is economically small and it is not significant at conventional levels.

Even though it does not seem to be the case that female officers get selectively sent to calls related to domestic violence, one might still be concerned that the type of domestic violence incidents to which at least one female versus only male officers get dispatched are different in nature. To address this concern, and assess the validity of the research design,

²²This information was shared with us when I spoke to an 9-1-1 Operations Manager from SPD

I compare the characteristics of the domestic violence calls where at least one female officer was sent to those in which only men were sent. I use the call priority assigned by the call taker as well as the time (measured in seconds) between when the call came in and when the first officer(s) were dispatched. Further, since demographic characteristics of the victim and suspect are only recorded when the officers classified the incident as a crime, I rely on demographic characteristics at the census block group level from where the call came in from the 2016 American Economic Survey ²³. Specifically, I look at the percent of the census block group where the call originated from that is female, non-Hispanic white, as well as the unemployment rate. For this test, I use the specification discussed in section 3.2, and the universe of calls for service that the call taker assigned to DV label to. Results for this test, which can be found in Table 3, show that the characteristics studied are balanced between cases with and without at least one female officer. Coefficients are not only statistically insignificant, but also small in magnitude, which is consistent with the identifying assumption of the study.

4 Results

4.1 Main Results

Table 4 shows the results from estimating equation (1) on whether the final classification of the incident is domestic violence, whether the incident gets recorded as a crime and whether an arrest is made on the scene. It should be noted that while I do not have access to the gender of the complainant in cases in which the incident was not reported as a crime, given that most victims of domestic violence are women (Catalano, 2012), I view the results found as largely representing differential response by officer gender to incidents involving female victims.

Focusing first on column (1), I see that dispatching at least one female officer to domes-

²³There were 482 census block groups in Seattle in 2016

tic violence calls increases the probability that the final classification will stay as domestic violence by 1.65 percentage points, an effect of 2.8% with respect to the mean of only male teams. This indicates a higher willingness of teams that include female officers to formally record incidents as domestic violence with all the consequences that this entails. These include higher expected sanctions for offenders and more targeted resources for victims. In the state of Washington, a conviction with a domestic violence designation carries additional penalties such as the loss of gun rights (even in if convicted of a misdemeanor) and having to undergo treatment for domestic violence. Further, a misdemeanor DV charge is automatically upgraded to a felony if the offender has at least two previous convictions for other crimes of DV (such as for assault or harassment) within the previous ten years.

Turning to column (2), I see that the likelihood that the responding officers will report the incident as a crime is also increased by the presence of at least one female officer. More specifically, this probability increases by 0.86 percentage points, which corresponds to a 2.7% increase with respect to the mean. Conversely, when only men report to the scene of a domestic violence call, they are more inclined to view the situation as a civil matter that does not require police intervention. This is consistent with findings in [Chu and Sun \(2014\)](#), who using data from surveys found that male officers were more likely than female officers to support minimum police involvement and to tolerate domestic violence. This result is also in line with [Sukhtankar et al. \(2022\)](#) who, in the context of dedicated spaces for women in Indian police stations, find that registering of offenses is more likely when female officers run the desks. Domestic violence is a notoriously under-reported crime, with less than half of violent victimizations being reported to police ([Morgan and Truman, 2019](#)). This result suggests that dispatching at least one female officer, rather than only males, can help alleviate this problem, both by increasing the probability that the crime gets reported, and by signaling to victims that their case is taken seriously, which might in turn increase the probability that they choose to report future victimization.

Finally, column (3) shows that when it comes to an arrest being made at the scene, there

does not seem to be a difference in the overall probability of this taking place by the gender composition of the responding officers. One possible reason why there might not be any differences in the probability of an arrest being made, is that for some of these incidents, arrest is mandatory. This is, if officers believe that an assault related to domestic violence took place at most 4 hours before they arrived, then Washington state law dictates that officers must arrest the perpetrator. In order to see whether this indeed explains the null result found for arrests, and to better understand the dynamics behind the results found on reporting and the final classification, I next split up the sample of DV calls by the level of discretion awarded to officers.

4.2 Heterogeneity by Level of Officer Discretion

I next disaggregate cases into two different sub-categories of domestic violence incidents: those related to assaults or to protective orders, and those related to disturbances or threats. In order address endogeneity, when defining the two sub-groups I rely on the classification by the call taker. The first of these, which represent roughly 1/3 of incidents classified as DV by the call taker, are more severe in nature and, consequently, officers have limited discretion when deciding whether to arrest the perpetrator. On the other hand, the latter, which represent roughly 2/3 of incidents classified as DV by the call taker are less severe and thus officers will have more leeway and be able to use discretion when deciding whether to arrest the offender or not. ²⁴

Table 5 shows the results of this exercise. Each panel shows the results of each of the outcomes of interest for each sub-category of DV, and it shows how disturbances or threats,

²⁴In the case of assault, the law requires that officers arrest the perpetrator if they have reason to believe that an assault took place within the last four hours. This means that officer will have a little leeway here: if they believe that they do not have enough evidence of an assault taking place, even if the call taker believed so, or if the assault took place over 4 hours before they arrive at the scene. However, the discretion they have in these cases will be significantly lower than in cases where the call was related to a disturbance or threats.

which are the least severe offenses and where officers have the most discretion, is where the effects appear to be strongest. Panel A shows that, when at least one female officer is dispatched to DV calls, the likelihood of the final classification of the incident being also DV increases by around 2.2 p.p. and 1.5 p.p. for disturbances/threats and assaults/protective orders respectively. Given the difference in means of the dependent variable for each category, however, the implied percent effect is significantly bigger in the case of disturbances or threats. Turning to panel B, I see that the effect of having a female officer on the likelihood that the incident will be reported as a crime is of 1 p.p. for disturbances or threats. Given that these incidents are less severe in nature and often not considered to be crimes by responding officers, it amounts to an effect of 4.9% with respect to the mean of only male teams. For assaults or breaking protective orders, instead, I see that having a female officer increases the likelihood of a criminal report being written by 1.3 p.p., which amounts to a 2.3% increase, although the effect is not significant at conventional levels and it less than half in magnitude of the effect found for the less severe forms of DV. Finally, panel C shows that, while there was no overall effect of having a female officer on an arrest being made at the scene, this was in fact due to the cases in which arrest was mandatory. Looking at these cases where the law dictates that an arrest be made reveals a coefficient that is negligible in magnitude and not significant. Instead, when the call was related to a disturbance of threat, where there is more discretion, the likelihood of an arrest being made does vary depending on the gender composition of officers. Specifically, having at least one female officer increases the probability of an arrest being made at the scene by 0.61 p.p.. Given that only 7.8% of these incidents results in an arrest, this effect represents 7.9% of the mean.

These results are in line with the notion that that female officers tend to take less severe forms of domestic violence more seriously compared to their male counterparts, who are more inclined to dismiss these incidents as not constituting domestic violence or even crimes.

4.3 Effect on Recidivism

Given that teams with female officers are more likely to report the incident as a crime and arrest the suspect (in the case of disturbances or threats), which are precisely the actions that research has shown to reduce incidents of recidivism (see [Black et al., 2023](#), [Amaral et al., 2023](#) for some examples), I next explore whether female officers affect the likelihood of a future incident of domestic violence taking place (i.e. of recidivism).

Since I do not have a unique ID for each victim, to study recidivism, I leverage the address where the incident occurred. The addresses to which I have access to are blurred to represent the middle of the street where the incidents took place. I define future victimization as the occurrence of at least another incident that is also exogenously classified as domestic violence by the call taker at a later date within the same blurred address. It should be noted that the results from this section should be interpreted with caution, as a lower (higher) likelihood of a future call could reflect also a lower (higher) willingness to report by the victim. However, given past literature ([Miller and Segal, 2019](#), [Sun, 2007](#) among others), I would expect future likelihood of reporting to, if anything, increase after an experience with a female officer.

In figure [A.IV](#) I test whether there are any raw differences in the probability of a subsequent incident of domestic violence (as defined by the call taker) when at least one female officer was dispatched to the original incident. To do so, I create indicator variables for each incident that takes value 1 if there was another incident of domestic violence (as classified by the call taker) in the same blurred address within x days following the original incident, where $x \in [0, 30]$. Then the average for each day was calculated separately for incidents where at least one female officer responded and incidents in which every responding officer was male. The figure shows how, for most days following an incident, the probability of there being a subsequent incident is lower if there was a female officer present. In table [6](#) I formally test for these differences.

Table 6 shows the results on the short term of dispatching at least one female officer. Each column tests for the incidence of another call for domestic violence within the same address within $t \in \{15, 30, 60\}$ days of the original call. I focus on this time frame because the longer the time span considered, the higher the likelihood that the victim might have moved, and thus over-assigning repeat offenses. In appendix tables A.I and A.II, however, I show the results over longer time periods. Columns 1 and 2 of table 6 show that, when at least one female officer is dispatched, the likelihood of a future call for domestic violence within 15 and 30 days is reduced by 0.6 and 0.8 p.p. respectively. These effects correspond to 2.9 and 2.7% with respect to their means. Columns 3-5, however, show that these effects are not sustained over longer periods of time. Table 7 instead shows the results after splitting the one-year time interval into days 1-15, days 16-30 and days 31-60.

5 Mechanisms and Robustness

In this section I test the robustness the main results and explore the mechanisms driving them. I begin by testing whether the main results are robust to the inclusion of officer controls. I then test the robustness of the empirical model by controlling differently for the geography and time fixed effects that should allow me to isolate. To understand whether the results are due to female officers consistently policing differently or if instead they only recognize and respond differently to specific dynamics in domestic violence cases, I analyze the behavior of teams of responding officers that include women during incidents not classified as domestic violence by the call taker. I further also test whether teams with female officers exert more effort when handling domestic violence cases.

5.1 Robustness

I test the robustness of the results presented in two different ways. I first add controls for other officer characteristics. Namely I control for whether at least one of the officers is not

white non-Hispanic, as well as for the average experience of the team of responding officers. The experience of each officer is calculated as the number of days between when they joined the force and when the incident took place. ²⁵

I find that adding these controls does little to change the implied effects of having at least one female officer dispatched. Figure 2 plots the coefficient from the variable *has female officer* for each of the main outcomes as well as for the universe of all domestic violence related calls (in green), as well as for disturbances or threats and assaults or protective orders (in blue and orange respectively). Results including the coefficient for having at least one non white non-Hispanic and of the average experience of the officers can be found on table 2. Having at least one minority does not seem to affect the probability of the final classification being DV, of a criminal report being written or of an arrest being made at the scene. The average experience, on the other hand, does seem to matter: when the responding officers have been on the job for longer, the likelihood that the final classification is DV, that the incident gets reported as a crime and that there is an arrest on the scene is lower. Despite this, and despite the fact that female officers are less experienced on average, the effect of having at least one female officer remains largely unchanged.

Relatedly, we might also wonder whether the observed effects are due to gender diversity specifically or if diversity across other dimensions could produce similar results. To address this, I examine whether teams including at least one officer that is not white non-Hispanic handle domestic violence cases differently from all-white teams. Results can be found in Table A.VII and show that there is no significant difference in how they handle DV cases. This suggests that gender diversity, rather than diversity in general, is the relevant factor.

I then also test if results are robust to alternative specifications of the model. My empirical strategy relies on the assumption that conditional on geography and time fixed effects,

²⁵In both the calculation of the average experience and the presence of a racial minority, I only take into account the officers that were first dispatched to the scene.

I should be able to isolate as-good-as random variation in the gender of responding officers. My preferred specification does so by including sector-year-month-week FE as well as shift FE. However, one might control for geography and time in different ways, and I show that results stay largely unchanged when I do so. The top left panel of figure 3 shows that adding fixed effects for the beat from where the call originated from has little effect on the estimated coefficients of the effect of having at least one female responding officer. Further, the top right panel shows that the results are also robust to allowing the effect of the shift during which the call took place as well as the effect of the number of officers to vary by the police sector. Finally, the bottom panel shows that controlling for sector-year-month FE and week FE separately (as well as number of officers and shift fixed effects, as in the main specification) also does little to change the results found.

5.2 Mechanisms

5.2.1 Baseline Behavior of Female Officers

I test whether female officers handle *every* call for service differently than males, or if their differential responses are particular to cases they were told were related to domestic violence according to the call taker. To do so, I start by examining the subset of calls for service that are or could be violence between one or more people but that did not get assigned the domestic violence label by the call taker. This includes cases classified by the call taker as assaults, disorder, threats and fights. I then study the behavior of female officers in the remainder of calls that did not get classified as domestic violence by the call taker. Appendix tables A.III A.IV tests for conditional random assignment of officers to these calls, and shows that the characteristics of calls that get assigned at least one female responding officer do not differ from those that did not ²⁶.

Tables 8 and 9 shows the results of these exercises. Starting with table 8, and focusing on

²⁶The only characteristic for which the difference is statistically significant is the percent of the census block where the incident took place that is unemployed. However, it is only significant at the 10% level and the coefficient of 0.01 percentage points is not economically significant.

column 1, when at least one female officer is dispatched to incidents of violence that did not get classified as DV by the call taker but are inter-personal violence, the final classification is more likely to change to include the domestic violence label. The magnitude of 0.031 p.p. implies an 10.5% increase in the probability of the incident being classified as DV. This implies that the increased likelihood of female officers maintaining the DV label, as shown in table 4, is not merely due to their tendency to follow the call taker’s classification. Instead, this result is consistent with the idea of female officers being more willing than their male counterparts to label domestic violence as such, regardless of whether the call taker did, with all that it entails for victims and perpetrators. Further, it also points to the fact that teams with female officers might be more likely to catch type 2 errors in the classification by the call-taker. Column 1 of table 9 shows that also in cases that are not related to inter-personal violence, teams with female officers are still more likely to add the DV label. However, these are very rare events ²⁷.

When looking at whether the incident is reported as a crime, I also see that this is 6.4% more likely to occur if there is a female officer dispatched in cases of inter-personal violence and 6.3% more likely to occur in every other non-DV incidents. The fact that this effect is similar in magnitude to that found for disturbances related to DV, and even bigger than the one found for all DV, implies that the results found for domestic violence are not driven by female police officers changing their reporting practices when encountering domestic violence incidents. Instead, it would appear that female officers baseline behavior involves reporting incidents as crimes at a higher rate than their male counterparts. This means teams with female officers take *every* incident more seriously. Even though this result is not particular to DV cases, domestic violence victims still benefit from getting at least one female officer assigned.

²⁷The most common initial type classifications in this subsample to which the DV label is added include cases of unknown nature and peace-standby (these are cases in which police are present while parties in civil litigation exchange property or one of the parties is allowed to enter a residence building or vehicle to obtain property)

Finally, when examining arrests made at the scene, I find that the behavior of teams including female officers does not differ significantly from that of all-male teams. Since the decision to make an arrests when handling these incidents is discretionary, this indicates that the use of discretion in non-domestic violence (non-DV) cases does not vary depending on the gender composition of the team of responding officers. This in turn implies that the higher likelihood of arrests found in discretionary domestic violence cases is due to teams with female officers altering their arresting behavior when responding to domestic violence calls.

Even though arrest is not mandatory in cases of assault not related to domestic violence, and thus officers have discretion in all of the incidents analyzed in this section ²⁸ it might be still be the case that teams of officers that include women only differ in their arresting behavior when the case is related to a disturbance or threat. This would imply that the results found for arrests in DV related disturbances in table 5 would not reflect a change in behavior when handling DV cases, but instead that the severity at the time of the call is the relevant parameter. In order to understand whether this is the case, I also analyze disturbances or threats not related to DV separately. Table A.V shows the results of this exercise, and shows that, in these cases, the likelihood of the offender being arrested does not vary by the gender composition of responding officers, confirming that the results in Table 5 are unique to disturbances or threat that are DV related.

5.2.2 Effort

The results found in section 4.1 are consistent with the idea of female officers taking calls for service for domestic violence more seriously than their male counterparts, and thus exerting comparatively more effort when dispatched to these incidents. In this subsection I test for this claim directly. I use two different proxies for effort. The amount of time officers stay

²⁸Given that some incidents get classified as domestic violence by the officers but not the call taker, some of the assaults analyzed in this section might actually have called for a mandatory arrest after the officers determined that domestic violence was at play. However, this only happens in less than 3% of cases.

on the scene, and whether in their criminal reports, in addition to listing the main offense, officers also include additional minor offenses.

A key decision that officers will have to make once at the scene is how much information to gather and how thoroughly to investigate the incident. For instance, they can choose whether to actively search for potential witnesses, how meticulously to examine the scene, and the thoroughness with which they interview those involved and so on. Officers who engage in these activities will naturally spend more time at the scene. Therefore, how long officers are staying at the scene can be used as a proxy of the amount of effort exerted.

I define time at the scene was the minutes that pass between when the first officers arrive to the scene and when the incident is cleared (which corresponds to when officers have left the scene and are ready to be dispatched to another call). Using the full universe of domestic violence calls, I show that having at least one female officer on the team increases the time officers spend on the scene by 4%, as shown in column 1 of table 10. Columns 2 and 3 break down the full sample of DV calls into those cases related to disturbances or threats, and assaults or breaking of protective orders respectively; and shows that the effects are present and are similar for both types of offenses. Recall that for the sub-sample of DV cases related to disturbances or threats, teams of female officers were also more likely to write a criminal report against the perpetrator as well as arrest them. This might mechanically explain the 4.53% additional time spent at the scene for these offenses. However, the fact that teams with female officers are also spending more time at the scene in cases of assaults or protective orders (where they are not arresting perpetrators at a differential rate with respect to teams of only men, and display a relatively small difference in reporting) implies that the arresting behavior alone cannot explain this result. Therefore, these results are consistent with the notion of teams with female officers putting in more effort at the scene and provide a better service to victims of domestic violence. ²⁹

²⁹Results in levels instead of logarithms can be found in table A.VIII

Once officers determine that a criminal report is warranted, they next need to decide how many crimes to list in their report. Listing multiple offenses in the criminal report is among the most important optional actions responding officers can take to increase the chances of prosecution, especially when it comes to domestic violence cases (Ferguson and Douglas, 2016 , Nelson, 2013 ³⁰).

In the data, in cases when only one crime listed in the criminal report, the most common crime listed is "Assault Non-Aggravated DV". When instead multiple crimes are listed, the most common additional crimes are "Violation of DV Order", "Property Damage" and "Interfere with Report DV". ³¹ In this subsection I compare the likelihood of multiple charges being listed in police reports, conditional on a criminal report being written at all, by the gender composition of responding officers. In order to do so, I create a variable *Multiple Offenses Listed* that takes value 1 if more than 1 offense was listed in the criminal report, and zero when only one offense was listed. Note that this variable is not defined in cases in which the responding officers claimed that no crime took place, which means that I will be conducting this analysis for the subset of calls for service that resulted in a criminal report being written.

Table 11 shows the results from this analysis for the full sample, the subset of DV calls that the call taker classified as disturbances or threats and for the subset of DV calls that the call taker classified as either assaults or breaking of a protective order. I see that, when at least one female responding officer is dispatched, the probability that multiple offenses are listed (when a criminal report is written) increases by 2.22 pp, an effect that corresponds to 10% with respect to the mean of the dependent variable. Focusing on columns 2 and 3 reveals that this effect is driven by differences in cases that the call taker classified as disturbances or threats, which corresponds to the least severe cases in my sample. For this

³⁰This was also confirmed to us by a coordinator of law enforcement training from the Rhode Island Coalition Against Domestic Violence.

³¹This corresponds to the offender committing domestic violence and preventing or attempting to prevent the victim or a witness of the crime from calling 911, obtaining medical assistance, or making a report to any law enforcement official.

subset of calls, the presence of at least one female officer increases the probability of multiple charges being listed by 5.26 pp, which amounts to an effect of 22.9%. For assaults and breaking of protective orders, the coefficient is much smaller in magnitude and not significant at conventional levels. For incidents related to disturbances/threats, there may be less physical evidence compared to assaults or violations of protective orders. Consequently, these cases—often reliant on one person’s word against another’s—might particularly benefit from listing multiple charges, especially those like property damage, where physical evidence is more likely to be present. This approach could be crucial for holding the perpetrator accountable and advancing prosecution.

I test the results’ robustness to additional controls, specifically for officers’ experience. First, I control for the average experience of the team of responding officers. I then, I control for an indicator variable that equals one if at least one of the responding officers had been working patrol for less than a year at the time of the incident. These controls address the concern that teams with female officers are, on average, a bit less experienced, and that inexperienced teams might spend more time on scene not due to extra effort but due to a need for additional caution. Figure A.V shows that results remain largely unchanged.

As previously mentioned, the SPD does not record the gender of the complainant in cases deemed civil matters by patrol officers. However, this information is available when a criminal report is written. Thus, I can break down the results found in table 11 by gender of the victim. The results of this exercise can be found in appendix table A.IX. Panel A shows the results when at least one of the victims was a woman, while panel B restricts the sample to cases in which all the victims were male ³². I can see that the effects appear to be concentrated in cases in which there is a female victim.

One might also wonder whether teams with female officers *only* exert more effort in cases related to domestic violence. Tables A.X and A.XIII shows the results for cases that were

³²Some of these male victims could be underage

classified as violence between two or more people (assaults, fights, threats, disturbances) but not related to DV by the call taker, as well as for all other calls not related to DV respectively. They show how, when looking at all incidents, teams with female officers appear to stay longer. However, on these incidents, there is a disproportional amount of cases in which officers stay for less than one minute, claiming either they could not find the incident or that they provided assistance. Once we restrict to incidents in which officers stay for at least one minute, results change significantly. For cases that are inter-personal violence, teams with female officers stay for longer, but the effect is a lot smaller than for DV cases and only significant at the 90% level; while for non violent non-DV cases there is no difference in the time spent at the scene.³³ When it comes to listing multiple charges in their criminal reports, teams with female officers do not appear to do so more when it comes to cases of violence between two or more people, but they do when it comes other cases not related to DV. However, the rate is 1/4 of that of disturbances or threats related to domestic violence.

I further corroborate that the main findings are driven by teams with female officers treating DV cases differently and exerting comparatively more effort, rather than, for example, the victim being more prone to cooperate if there is a female officer present. To do so, I differentiate between cases in which the female officers were the most experienced in the team and cases in which the male officers were the most experienced. The underlying assumption is that the most experienced officer among the first responders is the one with the greatest influence on final classification, reporting and arresting decisions. Thus, if it was the case that the results are driven by the victim being more comfortable talking to police when there is a female officer, then we should observe the same results regardless of whether the female officer is the one making the decisions or not. On the other hand, if the results were driven by officers deciding to handle the case differently, then the effects should be concentrated among the incidents where the female officers were the most experienced. Figure A.VI shows evidence consistent, for the most part, with the former hypothesis. For

³³Table A.XII shows that restricting to incidents in which officers stay at least one minute for the domestic violence sample does little to affect the results.

final DV classification and arrest on the scene, and to a minor extent for reporting as a crime, the effects are larger and more significant when female officers are those with the greatest authority on the scene. This suggests that, while victims feeling more comfortable and being more cooperative can be playing a role, it cannot fully explain the results. Ultimately, the decisions of female officers do differ and such difference matter for DV outcomes.

The findings in this section highlight an important difference in how teams with female officers handle calls for domestic violence. The increase time spent at the scene, along with the higher tendency to list multiple offenses when writing police reports suggests that they approach these calls with more care and more thoroughly than their all male counterparts, which can help explain the differences found in tendencies to report incidents as crimes and arrest perpetrators. These actions can also serve as a signal to victims that their case is taken seriously.

6 Conclusion

In this paper I study the effect of dispatching at least one female officer to incidents of domestic violence using detailed administrative data from Seattle. To address endogeneity, I exploit conditional random assignment of officers to calls and focus on incidents classified as domestic violence by the call taker. Results show that teams that include female officers take these incidents more seriously and they are more likely to get involved. Specifically, the exogenously given domestic violence classification is more likely to remain and incidents are more likely to be reported as crimes when a female officer responds. Further, in incidents where officers have the most discretion, there is a higher likelihood of an arrest being made. These differences contribute to lower rate of recidivism in the short run when a female officer responds.

I also find that differential treatment of incidents extends beyond domestic violence. Even in cases that were not classified as domestic violence by the call taker, when at least one

female officer is dispatched the probability that the incident is taken seriously, as measured by the officer's decision of reporting it as a crime, is higher. In the subset of these cases that are related to inter-personal violence, I further show that teams with female officers are more likely to add a domestic violence label to the classification, confirming a higher willingness of female officers to classify incidents as domestic violence.

These findings suggest that female officers may bring a different perspective to policing, by taking a more serious and thorough approach to all types of incidents. By examining the differential behavior of police based on gender, I can explore the complexities of policing activities and provide evidence of *why* gender diversity in police departments is important and should be increased. The differential treatment of cases appears to be particularly important in domestic violence incidents, leading to more consistent and serious treatment of these cases, which proves beneficial, as evidenced by the lower rates of future victimization. My results highlight that although female officers are not currently dispatched selectively to domestic violence incidents, perhaps they should be.

7 Tables and Figures

Figure 1: Map of Seattle Police Beats, Sectors and Precincts

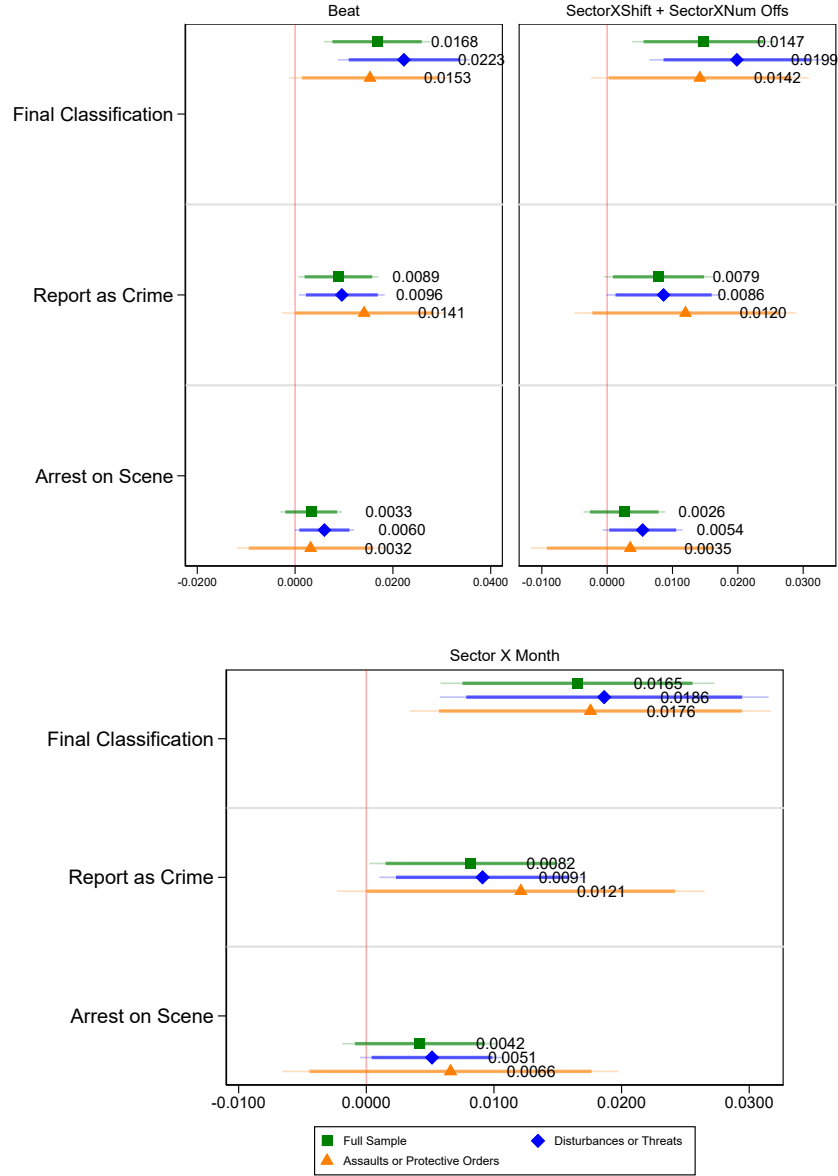

Notes: This figure shows a map of the 51 police beats contained in the 17 sectors which themselves are in contained in the 5 police precincts in Seattle. Each color depicts a precinct, while each shade of each color depicts a sector. The beats are labeled. Map obtained from th Seattle Police Department website: <https://www.seattle.gov/police/information-and-data/data/tweets-by-beat>

Figure 2: Robustness to Officer Controls

Notes: This figure shows robustness of the main results to the inclusion of officer controls. It plots the coefficient for the variable *has female officer* for different regressions. Officer controls refers to a dummy variable that takes value one when at least one of the responding officers belonged to a racial minority, as well as the average experience in years of the team of responding officers. *Full sample* corresponds to the entire universe of calls for service that were classified as domestic violence by the call taker. *Disturbances or threats* corresponds to the subset that the call taker classified as disturbances or threats related to domestic violence. *assaults or protective orders* corresponds to the subset of calls that the call taker classifies as assaults or breaking of protective orders related to domestic violence. Standards errors are clustered at the level of the team of responding officers initially dispatched to the scene. The confidence intervals correspond to the 95% and 90% level

Figure 3: Robustness to Model Specification

Notes: This figure shows robustness of the main results to different specifications of the model. It plots the coefficient for the variable *has female officer* for different regressions. The top left panel includes sector X week FE, sector X shift FE and sector X number of officers FE; while the top right panel includes sector X week, shift FE, number of officers FE and beat FE, and the bottom panel includes sector X year X month FE, shift FE, number of officers FE and week FE. *Full sample* corresponds to the entire universe of calls for service that were classified as domestic violence by the call taker. *Disturbances or threats* corresponds to the subset that the call taker classified as disturbances or threats related to domestic violence. *assaults or protective orders* corresponds to the subset of calls that the call taker classifies as assaults or breaking of protective orders related to domestic violence. Standards errors are clustered at the level of the team of responding officers initially dispatched to the scene. The confidence intervals correspond to the 95% level

Table 1: Summary Statistics

	All	Has Female Officer	Only Male Officers
<u>Call Characteristics</u>			
Has Female Officer	0.194 (0.396)	1.000 (0.000)	0.000 (0.000)
Number of Officers Dispatched	1.737 (0.599)	1.906 (0.573)	1.696 (0.598)
Call Priority	1.507 (0.562)	1.498 (0.554)	1.510 (0.564)
Time Between Call and Dispatch	1483.713 (4009.669)	1398.211 (3803.548)	1504.326 (4057.550)
Average Experience	8.440 (6.960)	7.654 (6.041)	8.629 (7.151)
Has Minority Officer	0.418 (0.493)	0.428 (0.495)	0.416 (0.493)
Pct White	0.601 (0.224)	0.602 (0.216)	0.601 (0.226)
Pct Women	0.492 (0.072)	0.486 (0.073)	0.493 (0.071)
Pct Unemployed	0.066 (0.062)	0.065 (0.064)	0.067 (0.062)
<u>Outcomes</u>			
Final Classification was DV	0.601 (0.490)	0.611 (0.487)	0.598 (0.490)
Reported as a Criminal Incident	0.326 (0.469)	0.331 (0.470)	0.325 (0.469)
Arrest on Scene	0.129 (0.335)	0.135 (0.342)	0.127 (0.333)
Observations	98644	19162	79482

Notes: This table reports mean, standard deviation (in parenthesis) and number of observations for each variable. *All* corresponds to the full sample of calls that the call taker classified as domestic violence, while *has female officer* corresponds to the subset of those in which at least one of the initially dispatched officers was a female, and *only male officers* to the subset in which all the initially dispatched officers were male. Average experience in years is the mean of the years that the responding officers dispatched to the call have been on the force. Pct white, women and unemployed corresponds to the pct of the population in the census block group that was white female and unemployed as measured in the 2016 ACS.

Table 2: Testing Conditional Random Assignment - Selection of Women into Domestic Violence Related Calls

	(1)
	Has Female Officer
Initially Classified as DV	0.0005 (0.0020)
Sector-year-month-week FE	Yes
Shift FE	Yes
Number of Officer FE	Yes
Observations	1498303
R^2	0.078

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Notes: This table reports the results of an OLS regression of a dummy variable that takes value 1 if there was a female officer in the patrol car on an indicator for whether the incident they were dispatched to was classified as domestic violence by the call taker. The regression was run using the universe of all calls for service. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers in the patrol car.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 3: Testing Conditional Random Assignment - Characteristics of Domestic Violence Calls

	(1)	(2)	(3)	(4)	(5)
	Call Priority	Time Between Call and Dispatch	Pct White	Pct Women	Pct Unemployed
Has Female Officer	-0.0029 (0.0054)	-56.0987 (40.9712)	0.0011 (0.0013)	-0.0008 (0.0006)	-0.0006 (0.0005)
Sector-year-month-week FE	Yes	Yes	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes	Yes	Yes
Number of Officer FE	Yes	Yes	Yes	Yes	Yes
Observations	97749	97749	97749	97749	97749
R^2	0.148	0.184	0.659	0.352	0.302

Notes: This table reports the results of an OLS regression of a dummy variable that takes value 1 if there was at least one female officer dispatched for a domestic violence call on call characteristics. Call priority refers to the priority assigned by the call taker. Time Between Call and Dispatch refers to the seconds between when the call was received and when the first officers were dispatched. Pct white, pct women and pct unemployed corresponds to the percent of the population in the census block group where the call originated that is white non-Hispanic, women and the percent that are unemployed respectively. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 4: Effect of Dispatching at Least One Female Officer to Calls for Domestic Violence

	(1)	(2)	(3)
	Final Classification was DV	Reported as a Criminal Incident	Arrest on Scene
Has Female Officer	0.0165*** (0.0056)	0.0086** (0.0042)	0.0033 (0.0032)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officer FE	Yes	Yes	Yes
Observations	97749	97749	97749
R^2	0.137	0.172	0.144
Mean All Male Officers	0.5985	0.3245	0.1267

Notes: This table shows estimates of the effect of dispatching at least one female officer to domestic violence calls on the final classification of the incident, whether the incident gets reported as a crime and whether an arrest was made at the scene. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 5: Heterogeneity by Type of Domestic Violence

	(1)	(2)
	Disturbances or Threats	Assaults or Protective Orders
Panel A: Final Classification was DV		
Has Female Officer	0.0219*** (0.0069)	0.0150* (0.0084)
Sector-year-month-week FE	Yes	Yes
Shift FE	Yes	Yes
Number of Officers FE	Yes	Yes
Observations	63727	30464
R^2	0.182	0.282
All Male Teams Mean	0.5439	0.7080
Panel B: Reported as a Criminal Incident		
Has Female Officer	0.0097** (0.0045)	0.0130 (0.0086)
Sector-year-month-week FE	Yes	Yes
Shift FE	Yes	Yes
Number of Officers FE	Yes	Yes
Observations	63727	30464
R^2	0.210	0.302
All Male Teams Mean	0.1994	0.5673
Panel C: Arrest on Scene		
Has Female Officer	0.0061** (0.0031)	0.0032 (0.0077)
Sector-year-month-week FE	Yes	Yes
Shift FE	Yes	Yes
Number of Officers FE	Yes	Yes
Observations	63727	30464
R^2	0.188	0.285
All Male Teams Mean	0.0775	0.2212

Notes: This table shows heterogeneous estimates by type of domestic violence call of the effect of dispatching at least one female officer to domestic violence calls on the final classification of the incident, whether the incident gets reported as a crime and whether an arrest was made at the scene. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 6: Effect of Dispatching at Least One Female Officer on Future Victimization

	(1)	(2)	(3)
	Another Incident Within 14 Days	Another Incident Within 30 Days	Another Incident Within 60 Days
Has Female Officer	-0.006* (0.004)	-0.008** (0.004)	-0.007 (0.004)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officer FE	Yes	Yes	Yes
Observations	97749	97749	97749
R^2	0.149	0.157	0.160
Mean	0.210	0.299	0.406

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Notes: This table shows estimates of the effect of dispatching at least one female officer to domestic violence related calls on the probability of a future call for domestic violence within 14, 30 and 60 days. *another incident withing t days* is an indicator that takes value one if, within t days of the incident, there is another call for service for domestic violence in the same blurred address. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 7: Effect of Dispatching at Least One Female Officer on Future Victimization

	(1)	(2)	(3)
	Within 15 Days	Between days 16-30	Between days 31-60
Has Female Officer	-0.006* (0.004)	-0.004 (0.003)	-0.001 (0.004)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officer FE	Yes	Yes	Yes
Observations	97749	97749	97749

Mean	0.210	0.165	0.246

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Notes: This table shows estimates of the effect of dispatching at least one female officer to domestic violence related calls on the probability of a future call for domestic violence. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 8: Effect of Dispatching at Least One Female Officer to Inter-Personal Violence Non-Domestic Violence Calls

	(1) Final Classification was DV	(2) Reported as a Criminal Incident	(3) Arrest on Scene
Has Female Officer	0.0031*** (0.0009)	0.0126*** (0.0024)	0.0012 (0.0012)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officer FE	Yes	Yes	Yes
Observations	333469	333469	333469
R^2	0.053	0.098	0.065
Mean All Male Officers	0.0295	0.1958	0.0510

Notes: This table shows estimates of the effect of dispatching at least one female officer to calls that were, at the time the call was placed, classified as assaults, fights, disturbances or threats not related to domestic violence calls on the final classification of the incident, whether the incident gets reported as a crime and whether an arrest was made at the scene. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 9: Effect of Dispatching at Least One Female Officer to Non-Violent Non-DV Calls

	(1)	(2)	(3)
	Final Classification was DV	Reported as a Criminal Incident	Arrest on Scene
Has Female Officer	0.0006** (0.0003)	0.0115** (0.0047)	-0.0003 (0.0006)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officers FE	Yes	Yes	Yes
Observations	1069315	1069315	1069315
R^2	0.016	0.075	0.027
All Male Teams Mean	0.0081	0.1813	0.0233

Notes: This table shows estimates of the effect of dispatching at least one female officer to calls that were, at the time the call was placed, not classified as domestic violence, nor as inter-personal violence (i.e. assault, fights, disturbances or threats) on the final classification of the incident, whether the incident gets reported as a crime and whether an arrest was made at the scene. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 10: Log Minutes at the Scene

	(1)	(2)	(3)
	Full Sample	Disturbances/Threats	Assaults/Protective Orders
Has Female Officer	0.0396*** (0.0150)	0.0447** (0.0186)	0.0494** (0.0195)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officers FE	Yes	Yes	Yes
Observations	96038	62540	29895
R^2	0.166	0.211	0.291
All Male Teams Mean	136.2113	124.5766	158.9459

Notes: This table shows the effects of dispatching at least one female officers on the time officers stay at the scene, where time at the scene is defined as the number of minutes that pass between when the first officers arrive at the scene and when they clear the call. Disturbances or threats corresponds to the subset that the call taker classified as a disturbance related to domestic violence or threats related to domestic violence. Assaults or protective orders corresponds to the subset that the call taker classified as an assault related to domestic violence or as breaking of a protective order of domestic violence. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table 11: Multiple Offenses

	Dependent variable: Multiple Offenses Listed=1		
	(1)	(2)	(3)
	Full Sample	Disturbances or Threats	Assaults or Protective Orders
Has Female Officer	0.0222*** (0.0074)	0.0526*** (0.0143)	0.0133 (0.0109)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officer FE	Yes	Yes	Yes
Observations	29573	9491	15344
R^2	0.272	0.371	0.350
Mean	0.2199	0.2302	0.2145

Standard errors in parentheses

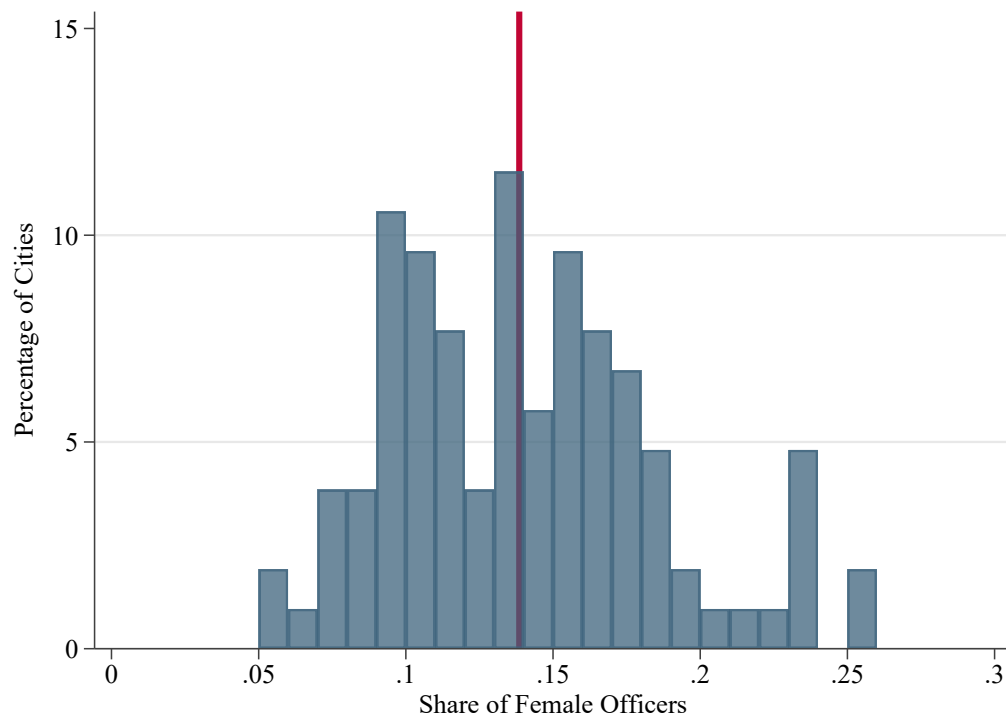

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Notes: This table shows the effects of dispatching at least one female officers on the number of offenses listed by the responding officers, conditional on having reported the incident as a crime. The full sample includes the subset of calls for service that the call taker classified as domestic violence and that the responding officers reported as a criminal incident. Disturbances or threats corresponds to the subset that the call taker classified as a disturbance related to domestic violence or threats related to domestic violence. Assaults or protective orders corresponds to the subset that the call taker classified as an assault related to domestic violence or as breaking of a protective order of domestic violence. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

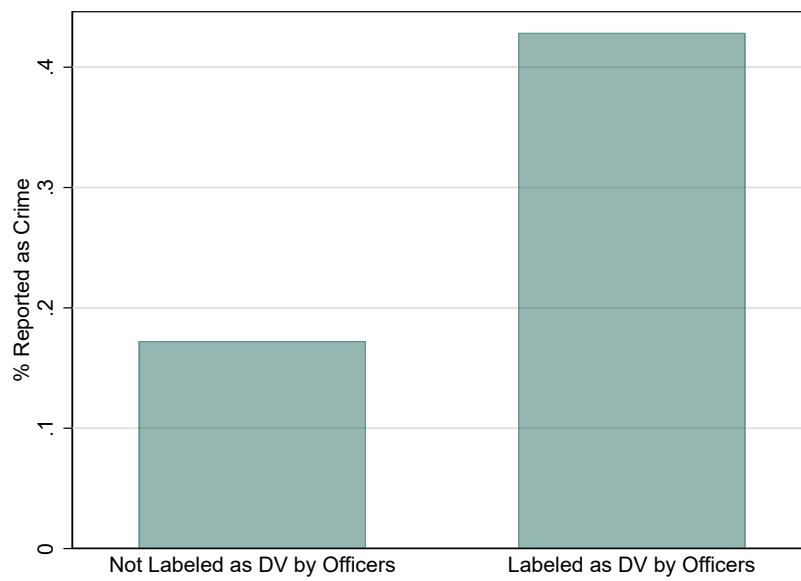

Appendix

Figure A.I: Distribution of Share of Female Officers in Major US Cities

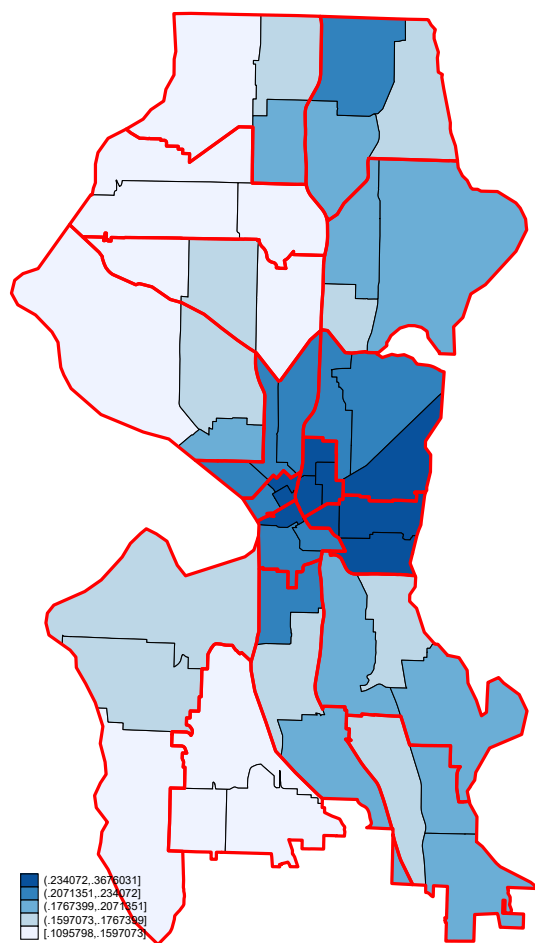

Notes: This figure shows the distribution of the percent of police officers that are female in 2013 in US cities with at least 250,000 people. The share was calculated using the 2013 wave of the LEMAS survey. The red line denotes where the Seattle Police Department lies within this distribution.

Figure A.II: Percent of Cases Classified as Crimes by DV Label

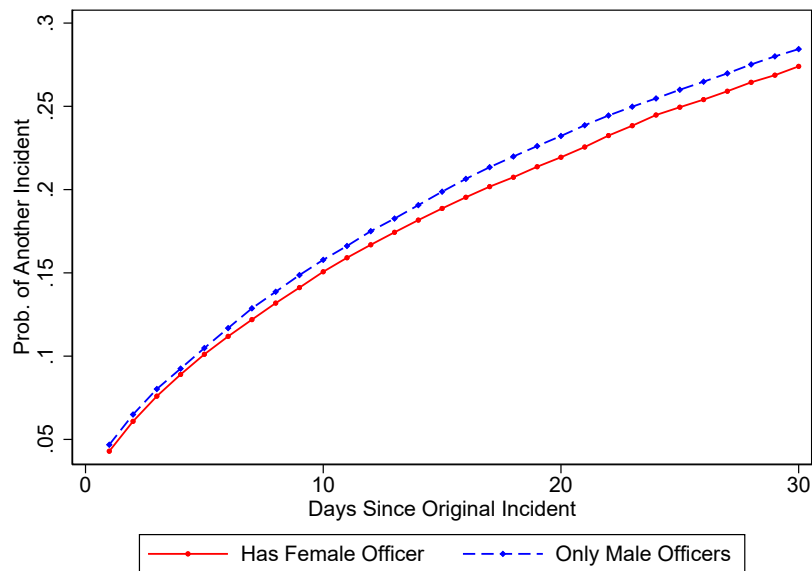

Notes: This figure shows the percent of cases classified as domestic violence by the call taker in which officers determined that a crime took place, separately for the cases in which officers labeled the offense as domestic violence and not (i.e. separately for the cases in which the officers determined that the domestic violence classification by the call taker was incorrect and the cases in which they believed that it was correct).

Figure A.III: Percent of Domestic Violence Cases with At Least One Female Officer by Beat

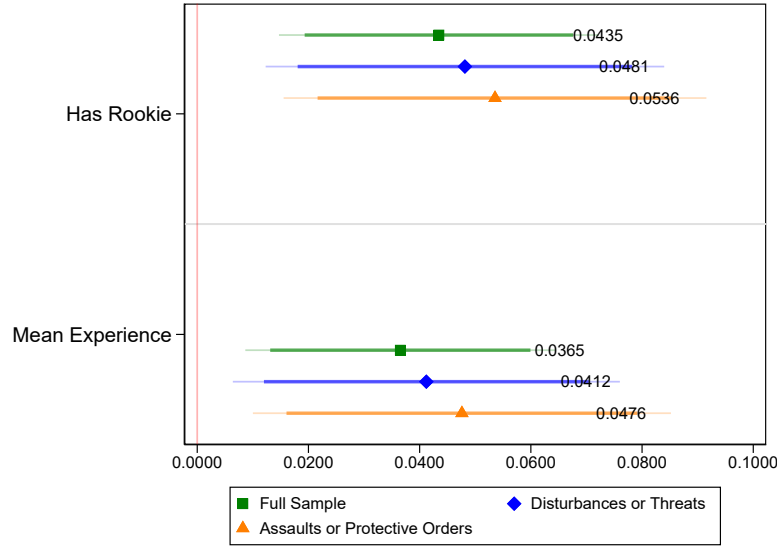

Notes: This figure shows the percent of cases classified as domestic violence by the call taker in each beat to which, throughout the time period studied (2012-2023), at least one female officer was initially dispatched. The red borders denote the limits of each sector.

Figure A.IV: Probability of Another DV Incident by Gender Composition of Responding Officers

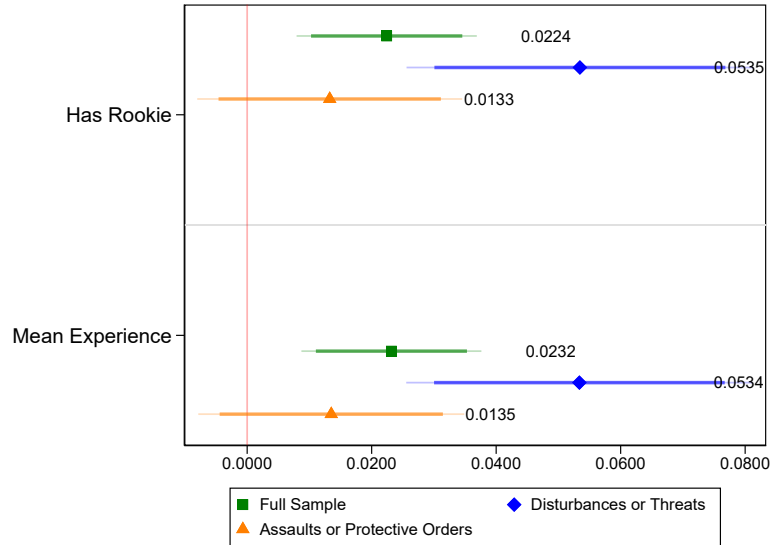

Notes: This figure shows the raw average probability of a subsequent incident of domestic violence taking place within each of the 30 days following a domestic violence call, by the gender composition of the responding officers of the original incident. The probability was calculated by creating indicator variables for each incident that takes value 1 if there was another incident of domestic violence (as classified by the call taker) in the same blurred address within x days following the original incident, where $x \in [0, 30]$. Then the average for each day was calculated separately for incidents where at least one female officer responded and incidents in which every responding officer was male.

Figure A.V: Robustness of Effort Measures to Officer Experience

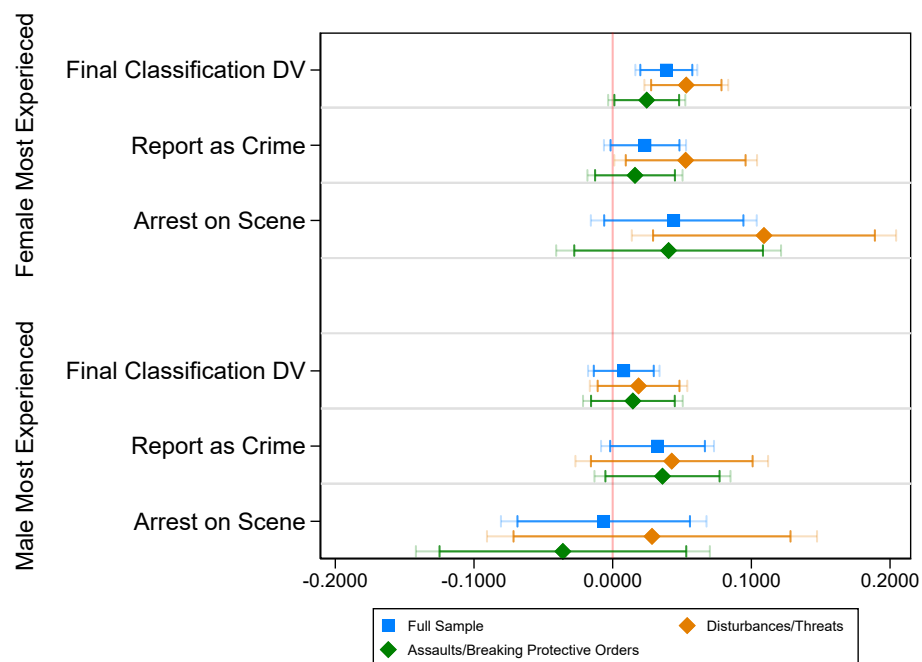

(a) Time at the Scene

(b) Multiple Charges

Notes: This figure shows robustness of the effort measures to the inclusion of controls for the experience of the officers. It plots the coefficient for the variable *has female officer* for different regressions: one controlling for the average experience of the first responding officers and one for an indicator that takes value 1 if at least one of the responding officers had been working as a patrol officer for less than an year at the time of the incident. *Full sample* corresponds to the universe of calls for service that were classified as domestic violence by the call taker. *Disturbances or threats* corresponds to the subset that the call taker classified as disturbances or threats. *assaults or protective orders* corresponds to the subset of calls that the call taker classifies as assaults or breaking of protective orders. Standards errors are clustered at the level of the team of responding officers initially dispatched to the scene. The confidence intervals correspond to the 95% and 90% level

Figure A.VI: Percent of Domestic Violence Cases with At Least One Female Officer by Beat

Notes: This figure shows the results of having a female officer separately for the cases in which there was a female officer and a female officer was the most experienced, and the cases in which there was a female officer but there were also male officer(s) and the male officer(s) were more experienced than the female officer(s). Estimates are derived from equation 1. Standards errors are clustered at the level of the team of responding officers initially dispatched to the scene.

Table A.I: Effect of Dispatching at Least One Female Officer on Future Victimization

	(1)	(2)	(3)	(4)	(5)
	Another Incident Within 15 Days	Another Incident Within 30 Days	Another Incident Within 60 Days	Another Incident Within 180 Days	Another Incident Within 365 Days
Has Female Officer	-0.006* (0.004)	-0.008** (0.004)	-0.007 (0.004)	0.003 (0.004)	0.001 (0.004)

Observations	333469	333469	333469	333469	333469
R^2	0.078	0.114	0.558	0.395	0.271

Notes: This table reports the results of an OLS regression of a dummy variable that takes value 1 if there was at least one female officer dispatched call characteristics for calls that were classified by the call taker as assaults, fights, disturbances or threats, all not related to domestic violence. Call priority refers to the priority assigned by the call taker. Time Between Call and Dispatch refers to the seconds between when the call was received and when the first officers were dispatched. Pct white, pct women and pct unemployed corresponds to the percent of the population in the census block group where the call originated that is white non-Hispanic, women and the percent that are unemployed respectively. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A.V: Effect of Dispatching at Least One Female Officer to Non-DV Disturbance Incidents

	(1)	(2)	(3)
	Final Classification was DV	Reported as a Criminal Incident	Arrest on Scene
Has Female Officer	0.0024*** (0.0008)	0.0121*** (0.0024)	0.0009 (0.0012)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officer FE	Yes	Yes	Yes
Observations	199945	199945	199945
R^2	0.081	0.121	0.093
Mean	0.0178	0.1269	0.0312

Notes: This table shows estimates of the effect of dispatching at least one female officer to calls that were, at the time the call was placed, classified as disturbances or threats not related to domestic violence calls on the final classification of the incident, whether the incident gets reported as a crime and whether an arrest was made at the scene. Estimates are derived from equation 1. The variable *Keep call taker classification* is an indicator variable equal to 1 if the call taker and responding officers both classified the incident as a non domestic violence related assault, disturbance/threat, or fight. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A.VI: Robustness to Officer Controls

R^2	0.146	0.189	0.286
All Male Teams Mean	0.1256	0.0772	0.2165

Notes: This table shows the results from testing the robustness of the results to officer controls. *has minority officer* is dummy variable that takes value one when at least one of the responding officers is not non-hispanic white, and *average experience* the average experience in years of the team of responding officers first dispatched to the scene. *Full sample* corresponds to the entire universe of calls for service that were classified as domestic violence by the call taker. *Disturbances or threats* corresponds to the subset that the call taker classified as disturbances or threats related to domestic violence. *assaults or protective orders* corresponds to the subset of calls that the call taker classifies as assaults or breaking of protective orders related to domestic violence. Estimates are derived from equation 1 (with the added officer controls). Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A.VII: Robustness to Officer Controls

	(1)	(2)	(3)
	Final Classification was DV	Reported as a Criminal Incident	Arrest on Scene

Observations	98527	98527	98527
R^2	0.136	0.172	0.144
Mean	0.5995	0.3224	0.1272

Notes: This table shows the effect of dispatching at least one non-Hispanic white officers to incidents classified as domestic violence by the call taker on the probability that officers keep the classification as domestic violence, report the incident as a crime and arrest the perpetrator. *has minority officer* is dummy variable that takes value one when at least one of the responding officers is not non-Hispanic white. Estimates are derived from equation 1 (with the added officer controls). Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A.VIII: Minutes at the Scene

	(1)	(2)	(3)
	Full Sample	Disturbances/Threats	Assaults/Protective Orders
Has Female Officer	4.3945*** (1.4609)	5.0950*** (1.6971)	3.8918* (2.2522)
Sector-year-month-week FE	Yes	Yes	Yes

R^2	0.166	0.211	0.291
All Male Teams Mean	136.2113	124.5766	158.9459

Notes: This table shows the effects of dispatching at least one female officers on the time officers stay at the scene, where time at the scene is defined as the number of minutes that pass between when the first officers arrive at the scene and when they clear the call. Disturbances or threats corresponds to the subset that the call taker classified as a disturbance related to domestic violence or threats related to domestic violence. Assaults or protective orders corresponds to the subset that the call taker classified as an assault related to domestic violence or as breaking of a protective order of domestic violence. Estimates are derived from equation 1. The dependent variable is in levels, meaning it represents changes in minutes. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

All Male Teams Mean	0.1717	0.1790	0.1565

Standard errors in parentheses

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Notes: This table shows the effects of dispatching at least one female officers on the number of offenses listed by the responding officers, conditional on having reported the incident as a crime by gender of the victims. The full sample includes the subset of calls for service that the call taker classified as domestic violence and that the responding officers reported as a criminal incident. Disturbances or threats corresponds to the subset that the call taker classified as a disturbance related to domestic violence or threats related to domestic violence. Assaults or protective orders corresponds to the subset that the call taker classified as an assault related to domestic violence or as breaking of a protective order of domestic violence. *Female Victim* is an indicator variable that takes value 1 when at least one of the victims was a female. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A.X: Log Time at the Scene for Violent Non-DV Incidents

	(1)	(2)
	Log Minutes at the Scene	Log Minutes at the Scene
Has Female Officer	0.0470*** (0.0180)	0.0277* (0.0159)
Sector-year-month-week FE	Yes	Yes
Shift FE	Yes	Yes
Number of Officer FE	Yes	Yes
Minutes ≥ 1	No	Yes
Observations	318949	312039
R^2	0.092	0.101
All Male Teams Mean	85.6745	87.6969

Notes: This table shows the effects of dispatching at least one female officers on the time officers stay at the scene for the subset of calls classified as assault, fights, disturbances, threats not related to domestic violence by the call taker. Time at the scene is defined as the number of minutes that pass between when the first officers arrive at the scene and when they clear the call. Estimates are derived from equation 1. Column 1 shows the results for the entire sample, while column 2 restricts the analysis for the cases in which officers stayed at the scene for at least one minute. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A.XI: Log Time at the Scene for Non-Violent Non-DV Incidents

	(1)	(2)
	Log Minutes at the Scene	Log Minutes at the Scene
Has Female Officer	0.0320*	0.0041
	(0.0188)	(0.0166)
Sector-year-month-week FE	Yes	Yes
Shift FE	Yes	Yes
Number of Officer FE	Yes	Yes
Minutes ≥ 1	No	Yes
Observations	1015715	991723
R^2	0.043	0.050
All Male Teams Mean	84.2189	86.3710

Notes: This table shows the effects of dispatching at least one female officers on the time officers stay at the scene for the subset of calls that the call taker did not classify as domestic violence nor violence between two or more people (i.e. as assault, fights, disturbances, threats). Time at the scene is defined as the number of minutes that pass between when the first officers arrive at the scene and when they clear the call. Estimates are derived from equation 1. Column 1 shows the results for the entire sample, while column 2 restricts the analysis for the cases in which officers stayed at the scene for at least one minute. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A.XII: Log Time at the Scene for Domestic Violence Incidents

	(1)	(2)	(3)
	Full Sample	Disturbances/Threats	Assaults/Protective Orders
Has Female Officer	0.0341** (0.0147)	0.0380** (0.0182)	0.0424** (0.0190)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officer FE	Yes	Yes	Yes
Minutes ≥ 1	Yes	Yes	Yes
Observations	95777	62335	29828
R^2	0.170	0.216	0.295
Mean	136.6055	124.9676	159.2258

Notes: his table shows the effects of dispatching at least one female officers on the time officers stay at the scene on incidents classified as domestic violence by the call taker, restricting to cases in which officers stay for at least one minute. Time at the scene is defined as the number of minutes that pass between when the first officers arrive at the scene and when they clear the call. Disturbances or threats corresponds to the subset that the call taker classified as a disturbance related to domestic violence or threats related to domestic violence. Assaults or protective orders corresponds to the subset that the call taker classified as an assault related to domestic violence or as breaking of a protective order of domestic violence. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Table A.XIII: Multiple Charges - All non-DV incidents

	(1) All Non-DV	(2) Violent Non-DV	(3) Non-Violent Non-DV
Has Female Officer	0.0055** (0.0024)	0.0067 (0.0046)	0.0053** (0.0027)
Sector-year-month-week FE	Yes	Yes	Yes
Shift FE	Yes	Yes	Yes
Number of Officer FE	Yes	Yes	Yes
Observations	259769	64335	194212
R^2	0.074	0.175	0.095
Mean	0.1235	0.1868	0.1029

Notes: This table shows the effects of dispatching at least one female officers on the number of offenses listed on criminal reports by the responding officers, conditional on having reported the incident as a crime. All non-DV refers to all incidents that the call taker did not classify as domestic violence and that the responding officers reported as a criminal incident. Violent non-dv corresponds to the subset in which the call taker classified as assault, fights, threats or disturbances, while non-violent non-dv refers to the remaining cases that the call taker did not say were DV related. Estimates are derived from equation 1. Standards errors are reported in parenthesis and are clustered at the level of the team of responding officers initially dispatched to the scene.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$
